## Lossless Compression Algorithms

[7.1 Introduction](#)

[7.2 Basics of Information Theory](#)

[7.3 Run-Length Coding](#)

[7.4 Variable-Length Coding \(VLC\)](#)

[7.5 Dictionary-based Coding](#)

[7.6 Arithmetic Coding](#)

[7.7 Lossless Image Compression](#)

## 7.1 Introduction

- **Compression:** the process of coding that will effectively reduce the total number of bits needed to represent certain information.

**Fig. 7.1:** A General Data Compression Scheme.

## Introduction (Cont'd)

- If the compression and decompression processes induce no information loss, then the compression scheme is **lossless**; otherwise, it is **lossy**.
- Compression ratio:

$$\text{compression ratio} = \frac{B_0}{B_1} \quad (7.1)$$

$B_0$  - number of bits before compression

$B_1$  - number of bits after compression

## 7.2 Basics of Information Theory

- The *entropy*  $\eta$  of an information *source* with alphabet  $S = \{s_1, s_2, \dots, s_n\}$  is:

$$\eta = H(S) = \sum_{i=1}^n p_i \log_2 \frac{1}{p_i} \quad (7.2)$$

$$= - \sum_{i=1}^n p_i \log_2 p_i \quad (7.3)$$

$p_i$  - probability that symbol  $s_i$  will occur in  $S$ .

$\log_2 \frac{1}{p_i}$  - indicates the amount of information (self-information as defined by Shannon) contained in  $s_i$ , which corresponds to the number of bits needed to encode  $s_i$ .

# Distribution of Gray-Level Intensities

Fig. 7.2: Histograms for Two Gray-level Images.

- Fig. 7.2(a) shows the histogram of an image with *uniform* distribution of gray-level intensities, i.e.,  $\forall i \ p_i = 1/256$ . Hence, the entropy of this image is:

$$\log_2 256 = 8 \quad (7.4)$$

- Fig. 7.2(b) shows the histogram of an image with two possible values. Its entropy is 0.92.

# Entropy and Code Length

- As can be seen in Eq. (7.3): the entropy  $\eta$  is a weighted-sum of terms  $\log_2 \frac{1}{p_i}$  ; hence it represents the *average* amount of information contained per symbol in the source  $S$ .
- The entropy  $\eta$  specifies the lower bound for the average number of bits to code each symbol in  $S$ , i.e.,

$$\eta \leq \bar{l} \quad (7.5)$$

$\bar{l}$  - the average length (measured in bits) of the codewords produced by the encoder.

## 7.3 Run-Length Coding

- **Memoryless Source:** an information source that is independently distributed. Namely, the value of the current symbol does not depend on the values of the previously appeared symbols.
- Instead of assuming memoryless source, *Run-Length Coding (RLC)* exploits memory present in the information source.
- **Rationale for RLC:** if the information source has the property that symbols tend to form continuous groups, then such symbol and the length of the group can be coded.

## 7.4 Variable-Length Coding (VLC)

### 7.4.1 Shannon-Fano Algorithm

— a top-down approach

1. Sort the symbols according to the frequency count of their occurrences.
2. Recursively divide the symbols into two parts, each with approximately the same number of counts, until all parts contain only one symbol.

An Example: coding of “HELLO”

Symbol	H	E	L	O
Count	1	1	2	1

Frequency count of the symbols in “HELLO”.

(a)

(b)

(c)

Fig. 7.3: Coding Tree for HELLO by Shannon-Fano.

**Table 7.1: Result of Performing Shannon-Fano on HELLO**

Symbol	Count	$\text{Log}_2$	Code	# of bits used
L	2	1.32	0	2
H	1	2.32	10	2
E	1	2.32	110	3
O	1	2.32	111	3
TOTAL # of bits:				10

(a)

(b)

**Fig. 7.4:** Another coding tree for HELLO by Shannon-Fano.

**Table 7.2:** Another Result of Performing Shannon-Fano on HELLO (see Fig. 7.4)

Symbol	Count	$\text{Log}_2$	Code	# of bits used
L	2	1.32	00	4
H	1	2.32	01	2
E	1	2.32	10	2
O	1	2.32	11	2
TOTAL # of bits:				10

## 7.4.2 Huffman Coding

### ALGORITHM 7.1 Huffman Coding Algorithm

— a bottom-up approach

1. Initialization: Put all symbols on a list sorted according to their frequency counts.
2. Repeat until the list has only one symbol left:
  - 1) From the list pick two symbols with the lowest frequency counts. Form a Huffman subtree that has these two symbols as child nodes and create a parent node.
  - 2) Assign the sum of the children's frequency counts to the parent and insert it into the list such that the order is maintained.
  - 3) Delete the children from the list.
3. Assign a codeword for each leaf based on the path from the root.

(a)

(b)

(c)

Fig. 7.5: Coding Tree for "HELLO" using the Huffman Algorithm.

## Huffman Coding (Cont'd)

In Fig. 7.5, new symbols P1, P2, P3 are created to refer to the parent nodes in the Huffman coding tree. The contents in the list are illustrated below:

After initialization: L      H      E      O

After iteration (a): L      P1      H

After iteration (b): L      P2

After iteration (c): P3

# Properties of Huffman Coding

1. **Unique Prefix Property:** No Huffman code is a prefix of any other Huffman code - precludes any ambiguity in decoding.
2. **Optimality:** *minimum redundancy code* - proved optimal for a given data model (i.e., a given, accurate, probability distribution):
  - The two least frequent symbols will have the same length for their Huffman codes, differing only at the last bit.
  - Symbols that occur more frequently will have shorter Huffman codes than symbols that occur less frequently.
  - The average code length for an information source  $S$  is strictly less than  $\eta + 1$ . Combined with Eq. (7.5), we have:

$$\bar{l} < \eta + 1 \quad (7.6)$$

# Extended Huffman Coding

- **Motivation:** All codewords in Huffman coding have integer bit lengths. It is wasteful when  $p_i$  is very large and hence  $\log_2 \frac{1}{p_i}$  is close to 0.
- Why not group several symbols together and assign a single codeword to the group as a whole?
- **Extended Alphabet:** For alphabet  $S = \{s_1, s_2, \dots, s_n\}$ , if  $k$  symbols are grouped together, then the *extended alphabet* is:

$$S^{(k)} = \overbrace{\{s_1 s_1 \dots s_1, s_1 s_1 \dots s_2, \dots, s_1 s_1 \dots s_n, s_1 s_1 \dots s_2 s_1, \dots, s_n s_n \dots s_n\}}^{k \text{ symbols}}.$$

— the size of the new alphabet  $S^{(k)}$  is  $n^k$ .

## Extended Huffman Coding (Cont'd)

- It can be proven that the average # of bits for each symbol is:

$$\eta \leq \bar{l} < \eta + \frac{1}{k} \quad (7.7)$$

An improvement over the original Huffman coding, but not much.

- **Problem:** If  $k$  is relatively large (e.g.,  $k \geq 3$ ), then for most practical applications where  $n \gg 1$ ,  $n^k$  implies a huge symbol table — impractical.

## EXTENDED HUFFMAN EXAMPLE

As an explicit example of the power of Extended Huffman Coding, let's construct a binary Huffman code for a source  $S$  with three symbols  $A$ ,  $B$  and  $C$ , having probabilities 0.6, 0.3, and 0.1, respectively.

We're interested in what is the average codeword length, in bits per symbol.

In comparison, let's also look at the value of the entropy of this source.

Huffman gives:

A: 1; B: 00; C: 01;

Average =  $0.1 \times 2 + 0.3 \times 2 + 0.6 \times 1 = 1.4$  bits/symbol

Let's now *extend* this code by grouping symbols into 2-character groups — useful for VQ (Chapter 8). Compare the performance now, in bits per original source symbol, with the best possible.

Tree is as below:

**Fig. 7.6:** Huffman Tree for Extended Alphabet

Codeword bitlengths are:

Symbol group	Probability	Codeword	Bitlength
AA	.36	0	1
AB	.18	100	3
BA	.18	101	3
CA	.06	1100	4
AC	.06	1101	4
BB	.09	1110	4
BC	.03	11110	5
CB	.03	111110	6
CC	.01	111111	6

$$\begin{aligned}
 \text{Average} &= 0.5 \times (0.36 + 3 \times 0.18 + 3 \times 0.18 + 4 \times 0.09 + 4 \times 0.06 + \\
 &4 \times 0.06 + 5 \times 0.03 + 6 \times 0.03 + 6 \times 0.01) \\
 &= 1.3350 \text{ (recall, was 1.4 for length-1 symbols).}
 \end{aligned}$$

The best possible is the entropy, given by:

$$H = -0.6 \times \log_2 0.6 - 0.3 \times \log_2 0.3 - 0.1 \times \log_2 0.1 \approx 1.2955.$$

## 7.4.3 Adaptive Huffman Coding

- **Adaptive Huffman Coding:** statistics are gathered and updated dynamically as the data stream arrives.

ENCODER

-----

```
Initial_code();
```

```
while not EOF
```

```
{
```

```
    get(c);
```

```
    encode(c);
```

```
    update_tree(c);
```

```
}
```

DECODER

-----

```
Initial_code();
```

```
while not EOF
```

```
{
```

```
    decode(c);
```

```
    output(c);
```

```
    update_tree(c);
```

```
}
```

## Adaptive Huffman Coding (Cont'd)

- *Initial\_code* assigns symbols with some initially agreed upon codes, without any prior knowledge of the frequency counts.
- *update\_tree* constructs an Adaptive Huffman tree.

It basically does two things:

- a) increments the frequency counts for the symbols (including any new ones).
  - b) updates the configuration of the tree.
- The *encoder* and *decoder* must use exactly the same *initial\_code* and *update\_tree* routines.

# Notes on Adaptive Huffman Tree Updating

- Nodes are numbered in order from left to right, bottom to top. The numbers in parentheses indicates the count.
- The tree must always maintain its *sibling* property, i.e., all nodes (internal and leaf) are arranged in the order of increasing counts.

If the sibling property is about to be violated, a *swap* procedure is invoked to update the tree by rearranging the nodes.

- When a swap is necessary, the farthest node with count  $N$  is swapped with the node whose count has just been increased to  $N + 1$ .

(a) A Huffman tree

(b) Receiving 2nd 'A' triggered a swap

(c-1) A swap is needed after receiving 3rd 'A'

(c-2) Another swap is needed

(c-3) The Huffman tree after receiving 3rd 'A'

Fig. 7.7: Node Swapping for Updating an Adaptive Huffman Tree

## Another Example: Adaptive Huffman Coding

- This is to clearly illustrate more implementation details. We show exactly what *bits* are sent, as opposed to simply stating how the tree is updated.
- An additional rule: if any character/symbol is to be sent the first time, it must be preceded by a special symbol, NEW. The initial code for NEW is 0. The *count* for NEW is always kept as 0 (the count is never increased); hence it is always denoted as NEW:(0) in Fig. 7.7.

**Table 7.3:** Initial code assignment for AADCCDD using Adaptive Huffman Coding.

Initial Code	
-----	
NEW:	0
A:	00001
B:	00010
C:	00011
D:	00100
	.
	.
	.

Fig. 7.8: Adaptive Huffman tree for AADCCDD.

Fig. 7.8 (Cont'd): Adaptive Huffman tree for AADCCDD.

**Table 7.4:** Sequence of symbols and codes sent to the decoder

Symbol	NEW	A	A	NEW	D	NEW	C	C	D	D
Code	0	00001	1	0	00100	00	00011	001	101	101

- It is important to emphasize that the code for a particular symbol changes during the adaptive Huffman coding process.

For example, after AADCCDD, when the character D overtakes A as the most frequent symbol, its code changes from 101 to 0.

- The “Squeeze Page” on this book’s web site provides a Java applet for adaptive Huffman coding.

## 7.5 Dictionary-based Coding

- LZW uses fixed-length codewords to represent variable-length strings of symbols/characters that commonly occur together, e.g., words in English text.
- The LZW encoder and decoder build up the same dictionary dynamically while receiving the data.
- LZW places longer and longer repeated entries into a dictionary, and then emits the *code* for an element, rather than the string itself, if the element has already been placed in the dictionary.

## ALGORITHM 7.2 - LZW Compression

```
BEGIN
  s = next input character;
  while not EOF
  {
    c = next input character;

    if s + c exists in the dictionary
      s = s + c;
    else
    {
      output the code for s;
      add string s + c to the dictionary with a new code;
      s = c;
    }
  }
  output the code for s;
END
```

## Example 7.2 LZW compression for string “ABABBABCABABBA”

- Let's start with a very simple dictionary (also referred to as a “string table”), initially containing only 3 characters, with codes as follows:

Code	String
1	A
2	B
3	C

- Now if the input string is “ABABBABCABABBA”, the LZW compression algorithm works as follows:

S	C	Output	Code	String
			1	A
			2	B
			3	C
A	B	1	4	AB
B	A	2	5	BA
A	B			
AB	B	4	6	ABB
B	A			
BA	B	5	7	BAB
B	C	2	8	BC
C	A	3	9	CA
A	B			
AB	A	4	10	ABA
A	B			
AB	B			
ABB	A	6	11	ABBA
A	EOF	1		

- The output codes are: 1 2 4 5 2 3 4 6 1. Instead of sending 14 characters, only 9 codes need to be sent (compression ratio =  $14/9 = 1.56$ ).

## ALGORITHM 7.3 LZW Decompression (simple version)

```
BEGIN
  s = NIL;
  while not EOF
  {
    k = next input code;
    entry = dictionary entry for k;
    output entry;
    if (s != NIL)
      add string s + entry[0] to dictionary with a new code;
      s = entry;
  }
END
```

**Example 7.3:** LZW decompression for string “ABABBABCABABBA”.

Input codes to the decoder are 1 2 4 5 2 3 4 6 1.

The initial string table is identical to what is used by the encoder.

- The LZW decompression algorithm then works as follows:

S	K	Entry/output	Code	String
			1	A
			2	B
			3	C
NIL	1	A		
A	2	B	4	AB
B	4	AB	5	BA
AB	5	BA	6	ABB
BA	2	B	7	BAB
B	3	C	8	BC
C	4	AB	9	CA
AB	6	ABB	10	ABA
ABB	1	A	11	ABBA
A	EOF			

Apparently, the output string is “ABABBABCABABBA”, a truly lossless result!

---

## ALGORITHM 7.4 LZW Decompression (modified)

```
BEGIN
    s = NIL;
    while not EOF
    {
        k = next input code;
        entry = dictionary entry for k;

        /* exception handler */
        if (entry == NULL)
            entry = s + s[0];

        output entry;
        if (s != NIL)
            add string s + entry[0] to dictionary with a new code;
            s = entry;
    }
END
```

## LZW Coding (Cont'd)

- In real applications, the code length  $l$  is kept in the range of  $[l_0, l_{max}]$ . The dictionary initially has a size of  $2^{l_0}$ . When it is filled up, the code length will be increased by 1; this is allowed to repeat until  $l = l_{max}$ .
- When  $l_{max}$  is reached and the dictionary is filled up, it needs to be flushed (as in Unix *compress*, or to have the LRU (least recently used) entries removed.

## 7.6 Arithmetic Coding

- Arithmetic coding is a more modern coding method that usually out-performs Huffman coding.
- Huffman coding assigns each symbol a codeword which has an integral bit length. Arithmetic coding can treat the whole message as one unit.
- A message is represented by a half-open interval  $[a, b)$  where  $a$  and  $b$  are real numbers between 0 and 1. Initially, the interval is  $[0, 1)$ . When the message becomes longer, the length of the interval shortens and the number of bits needed to represent the interval increases.

## ALGORITHM 7.5 Arithmetic Coding Encoder

BEGIN

low = 0.0; high = 1.0; range = 1.0;

while (symbol != terminator)

{

get (symbol);

high = low + range \* Range\_high(symbol);

low = low + range \* Range\_low(symbol);

range = high - low;

}

output a code so that  $\text{low} \leq \text{code} < \text{high}$ ;

END

## Example: Encoding in Arithmetic Coding

Symbol	Probability	Range
A	0.2	[0, 0.2)
B	0.1	[0.2, 0.3)
C	0.2	[0.3, 0.5)
D	0.05	[0.5, 0.55)
E	0.3	[0.55, 0.85)
F	0.05	[0.85, 0.9)
\$	0.1	[0.9, 1.0)

(a) Probability distribution of symbols.

**Fig. 7.9:** Arithmetic Coding: Encode Symbols "CAEE\$"

**Fig. 7.9(b):** Graphical display of shrinking ranges.

## Example: Encoding in Arithmetic Coding

Symbol	Low	High	Range
	0	1.0	1.0
C	0.3	0.5	0.2
A	0.30	0.34	0.04
E	0.322	0.334	0.012
E	0.3286	0.3322	0.0036
\$	0.33184	0.33220	0.00036

(c) New *low*, *high*, and *range* generated.

**Fig. 7.9 (Cont'd):** Arithmetic Coding: Encode Symbols "CAEE\$"

## PROCEDURE 7.2 Generating Codeword for Encoder

BEGIN

    code = 0;

    k = 1;

    while (value(code) < low)

    {

        assign 1 to the kth binary fraction bit

        if (value(code) > high)

            replace the kth bit by 0

        k = k + 1;

    }

END

- The final step in Arithmetic encoding calls for the generation of a number that falls within the range  $[low, high)$ . The above algorithm will ensure that the shortest binary codeword is found.

## ALGORITHM 7.6 Arithmetic Coding Decoder

BEGIN

get binary code and convert to  
decimal value = value(code);

DO

{

find a symbol s so that

Range\_low(s) ≤ value < Range\_high(s);

output s;

low = Range\_low(s);

high = Range\_high(s);

range = high - low;

value = [value - low] / range;

}

UNTIL symbol s is a terminator

END

**Table 7.5:** Arithmetic coding: decode symbols “CAEE\$”

Value	Output Symbol	Range_low	Range_high	range
0.33203125	C	0.3	0.5	0.2
0.16015625	A	0.0	0.2	0.2
0.80078125	E	0.55	0.85	0.3
0.8359375	E	0.55	0.85	0.3
0.953125	\$	0.9	1.0	0.1

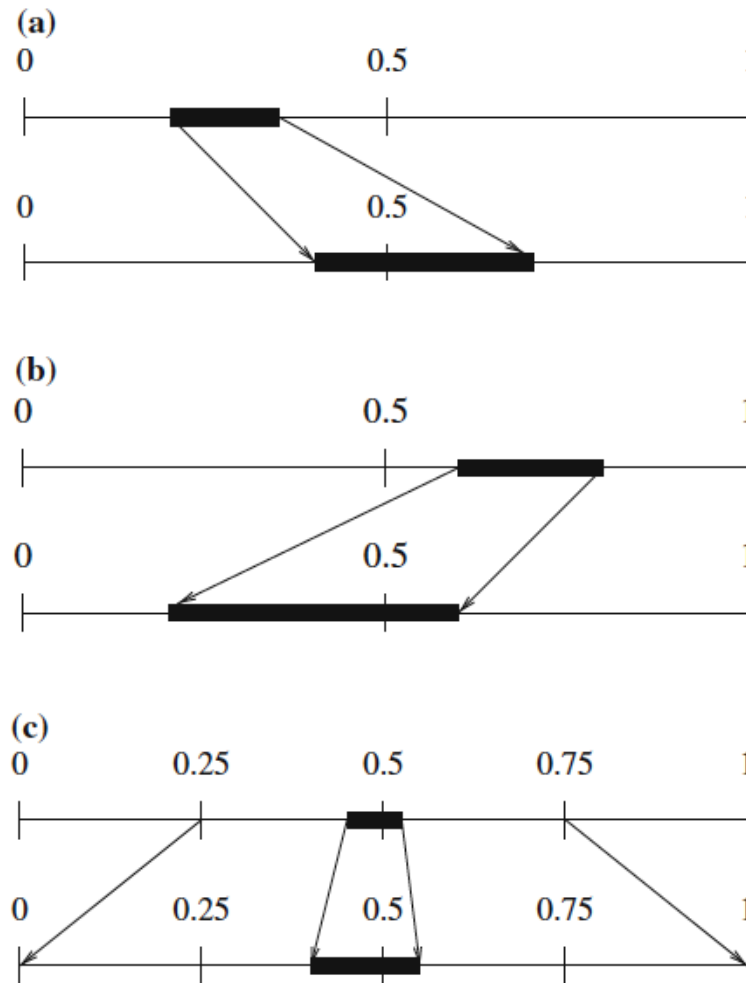

## 7.6.2 Scaling and Incremental Coding

- The basic algorithm described in the last section has the following *limitations* that make its practical implementation infeasible.
- When it is used to code long sequences of symbols, the tag intervals shrink to a very small range. Representing these small intervals requires very high-precision numbers.
- The encoder will not produce any output codeword until the entire sequence is entered. Likewise, the decoder needs to have the codeword for the entire sequence of the input symbols before decoding.

## Some key observations:

1. Although the binary representations for the *low*, *high*, and any number within the small interval usually require many bits, they always have the same MSBs (Most Significant Bits). For example, 0.1000110 for 0.5469 (low), 0.1000111 for 0.5547 (high).
2. Subsequent intervals will always stay within the current interval. Hence, we can output the common MSBs and remove them from subsequent considerations.

**Fig. 7.10:** Scaling in arithmetic coding.  
 (a) E1 Scaling, (b) E2 Scaling, (c) E3 Scaling.

## Procedure 7.3: (E1 and E2 Scalings in Arithmetic Coding).

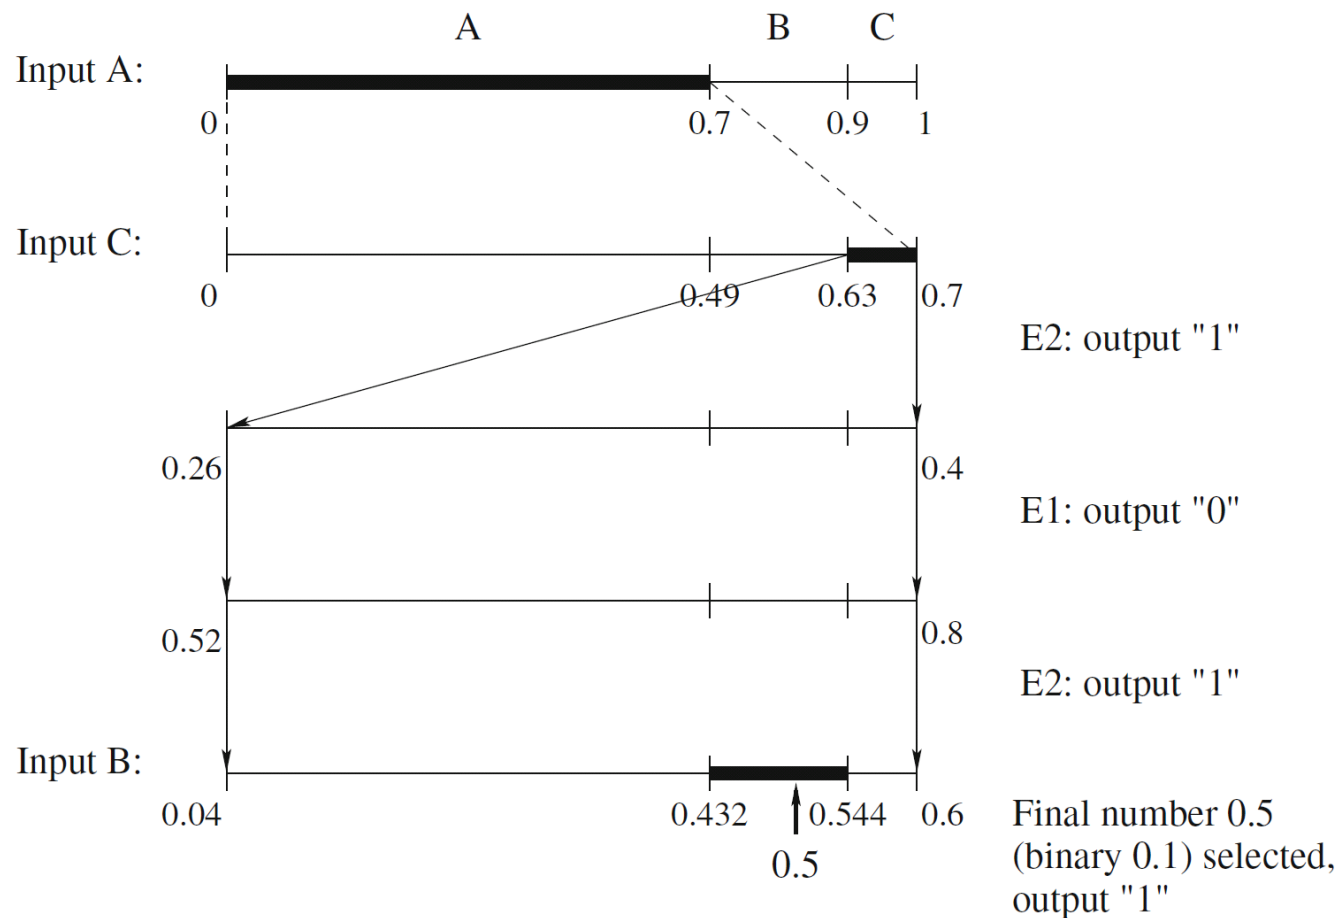

BEGIN

```
while (high <= 0.5) OR (low >= 0.5)
{ if (high <= 0.5)          // E1 scaling
  { output '0';
    low = 2 * low; high = 2 * high;
  }
else                        // E2 scaling
  { output '1';
    low = 2 * (low - 0.5); high = 2 * (high - 0.5);
  }
}
```

END

## Example 7.4: (Arithmetic Coding with Scaling and Incremental Coding).

- Assume we only have three symbols A, B, C, and their probabilities are: A: 0.7, B: 0.2, C: 0.1. Suppose the input sequence for this example is ACB, and both the encoder and decoder know that the length of the sequence is 3.

**Fig. 7.11:** Example: arithmetic coding with scaling and incremental coding–encoder

**Fig. 7.12:** Example: arithmetic coding with scaling and incremental coding–decoder

## E3 Scaling

- $N$  E3 scaling steps followed by an E1 is equivalent to an E1 followed by  $N$  E2 steps.
- $N$  E3 scaling steps followed by an E2 is equivalent to an E2 followed by  $N$  E1 steps.

Therefore, a good way to handle the signaling of the E3 scaling is: postpone until there is an E1 or E2.

- If there is an E1 after  $N$  E3 operations, send '0' followed by  $N$  '1's after the E1;
- if there is an E2 after  $N$  E3 operations, send '1' followed by  $N$  '0's after the E2.

## 7.6.3 Integer Implementation

- Uses only integer arithmetic. It is quite common in modern multimedia applications.
- Basically, the unit interval is replaced by a range  $[0, N)$ , where  $N$  is an integer, e.g. 255.
- Because the integer range could be so small, e.g.,  $[0, 255)$ , applying the scaling techniques similar to what was discussed above, now in integer arithmetic, is a necessity.
- The main motivation is to avoid any floating number operations.

## 7.6.4 Binary Arithmetic Coding

- Only use binary symbols, 0 and 1.
- The calculation of new intervals and the decision of which interval to take (first or second) are simpler.
- Fast Binary Arithmetic Coding (Q-coder, MQ-coder) was developed in multimedia standards such as JBIG, JBIG2, and JPEG-2000. The more advanced version, Context-Adaptive Binary Arithmetic Coding (CABAC) is used in H.264 (M-coder) and H.265.

**Fig. 7.13:** Binary arithmetic coding

## Procedure 7.4 (Procedures for Adaptive Arithmetic Coding).

ENCODER

-----

Initialization (reset counters)

```
while (symbol != terminator)
{
    get(symbol);
    encode(symbol);
    update stats and interval;
}
```

DECODER

-----

Initialization (reset counters)

```
while (symbol != terminator)
{
    decode(symbol);
    output(symbol);
    update stats and interval;
}
```

## Example 7.5: (Adaptive Binary Arithmetic Coding).

- Assume the input symbols to the encoder is 10001.
- Assume that both the encoder and decoder know the length of the sequence.

\*\* For clarity and simplicity, the scaling procedure (for E1, E2, etc.) will not be used.

**Fig. 7.14:** Adaptive binary arithmetic coding—encoder [input symbols:10001]

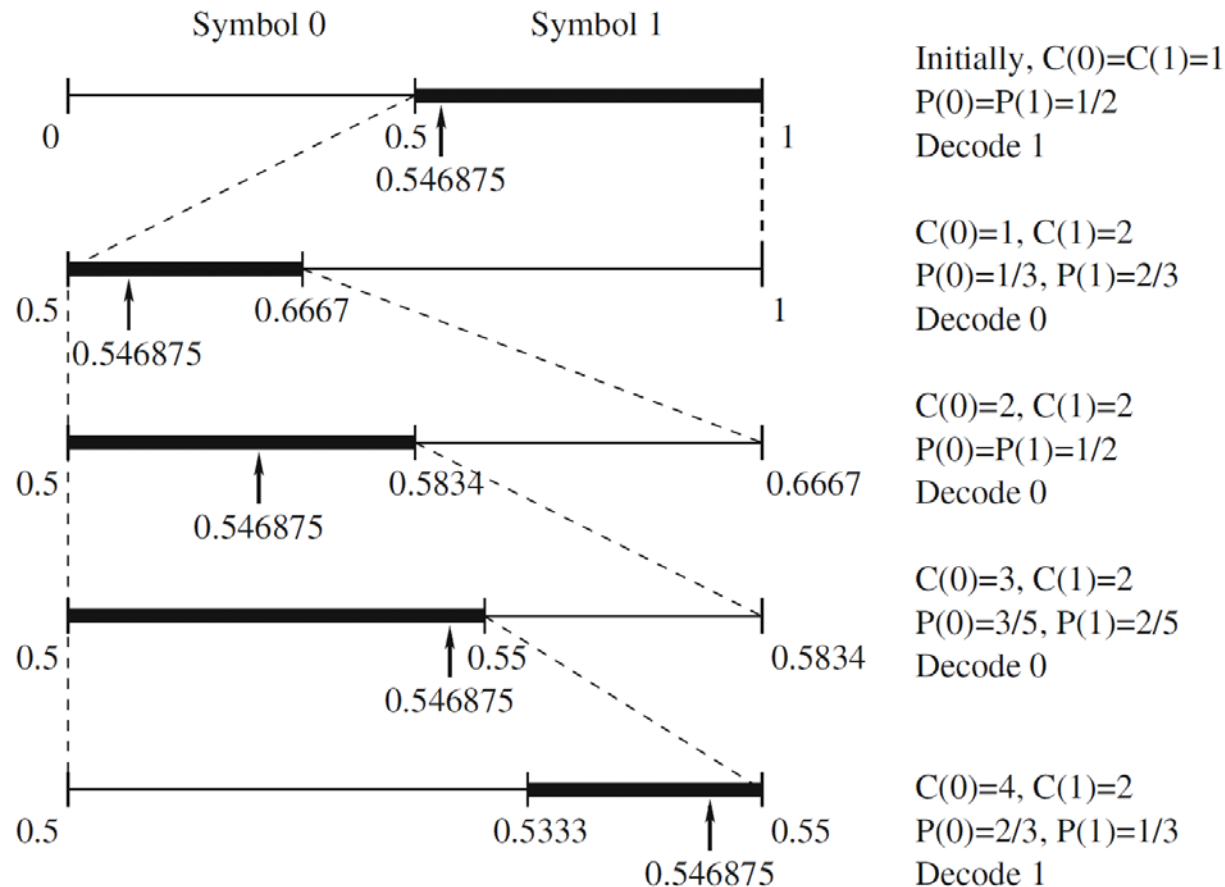

Fig. 7.15: Adaptive binary arithmetic coding—decoder. [input: 0.546875 (binary 0.100011)]

## 7.7 Lossless Image Compression

- Approaches of Differential Coding of Images:
  - Given an original image  $I(x, y)$ , using a simple difference operator we can define a difference image  $d(x, y)$  as follows:

$$d(x, y) = I(x, y) - I(x - 1, y) \quad (7.9)$$

or use the discrete version of the 2-D Laplacian operator to define a difference image  $d(x, y)$  as

$$d(x, y) = 4 I(x, y) - I(x, y - 1) - I(x, y + 1) - I(x + 1, y) - I(x - 1, y) \quad (7.10)$$

- Due to *spatial redundancy* existed in normal images  $I$ , the difference image  $d$  will have a narrower histogram and hence a smaller entropy, as shown in Fig. 7.9.

**Fig. 7.16:** Distributions for Original versus Derivative Images. (a,b): Original gray-level image and its partial derivative image; (c,d): Histograms for original and derivative images.

(This figure uses a commonly employed image called “Barb”.)

## 7.7.2 Lossless JPEG

- Lossless JPEG: A special case of the JPEG image compression.
- The Predictive method
  1. **Forming a differential prediction:** A predictor combines the values of up to three neighboring pixels as the predicted value for the current pixel, indicated by 'X' in Fig. 7.10. The predictor can use any one of the seven schemes listed in Table 7.6.
  2. **Encoding:** The encoder compares the prediction with the actual pixel value at the position 'X' and encodes the difference using one of the lossless compression techniques we have discussed, e.g., the Huffman coding scheme.

**Fig. 7.17:** Neighboring Pixels for Predictors in Lossless JPEG.

- **Note:** Any of A, B, or C has already been decoded before it is used in the predictor, on the decoder side of an encode-decode cycle.

## Table 7.6: Predictors for Lossless JPEG

Predictor	Prediction
P1	A
P2	B
P3	C
P4	$A + B - C$
P5	$A + (B - C) / 2$
P6	$B + (A - C) / 2$
P7	$(A + B) / 2$

**Table 7.7: Comparison with other lossless compression programs**

Compression Program	Compression Ratio			
	Lena	Football	F-18	Flowers
Lossless JPEG	1.45	1.54	2.29	1.26
Optimal Lossless JPEG	1.49	1.67	2.71	1.33
