Object Oriented Programming with C++

Unit-6 Polymorphism

Polymorphism

- Pointers in C++
- Pointers and Objects
- this pointer
- virtual and pure virtual functions
- Implementing polymorphism

Pointers in C++

Pointer variable

Pointer is a variable that holds a memory address, of another variable.

```
int a = 25;
int *p;
                                                   1000
                                25
p = &a;
                                                   2000
                               1000
cout<<"&a:"<<&a;
                     &a:1000
cout<<"p:"<<p;
                     p:1000
cout<<"&p:"<<&p;
                     &p:2000
                                          *Indicates value
cout<<"*p:"<<*p;
                      *p:25
                                           at address
cout<<"*(&a):"<<*(&a); *(&a):25
(*p)++;
                     *p:26
cout<<"*p:"<<*p;
cout<<"a:"<<a;
                     a:26
```

Pointer (Cont...)

Pointer to pointer is a variable that holds a memory address, of another pointer variable.

```
int a = 25;
                                        1000
                                                   2000
                                     p
                              25
int *p,**s;
                           a
                                                    3000
p = &a;
                              1000<
s = &p;
cout<<"\n*p:"<<*p;
                        *p:25
cout<<"\n*s:"<<*s;
                       *s:1000
cout<<"\n**s:"<<**s;
                        **s:25
                                    *(*(&p)):25
cout<<"\n*(*(&p)):"<<*(*(&p));
cout<<"\n***(&s):"<<***(&s);
                                    ***(&s):25
```

Pointer to arrays

```
int main ()
   int arr[5] = \{10,20,30,40,50\};
   int *ptr;
                      Also, written as
                       ptr = arr;
   ptr = &arr[0];
   for ( int i = 0; i < 5; i++ )
       cout <<"*(ptr+" << i <<"):";
       cout <<*(ptr + i) << endl;</pre>
   return 0;
```

```
0 10 1000 <del>ptr</del>
1 20 1002
2 30 1004
3 40 1006
4 50 1008
```

Output:

*(ptr + 0) : 10 *(ptr + 1) : 20 *(ptr + 2) : 30 *(ptr + 3) : 40 *(ptr + 4) : 50

Pointers and objects

 Just like pointers to normal variables and functions, we can have pointers to class members (variables and methods).

```
class ABC
                                          When accessing
  public:
                                          members of a class
  int a=50;
                                          given a pointer to an
                                          object, use the
int main()
                                          arrow
                                          (->) operator
                                          instead of the dot
  ABC ob1;
  ABC *ptr;
                                          operator.
  ptr = \&ob1;
  cout << ob1.a;</pre>
  cout << ptr->a; // Accessing member with pointer
```

Pointers and objects (Cont...)

```
class demo{
   int i;
   public:
     demo(int x)
       i=x;
     int getdata(){
       return i;}
int main()
  demo d(55),*ptr;
  ptr=&d;
   cout<<ptr->getdata();
```

Pointers and objects (Cont...)

```
class demo{
   int i;
                                  When a pointer incremented it
   public:
                                    points to next element of its
     demo(int x){
                                    type.
        i=x; }
                                    An integer pointer will point to
      int getdata(){
                                    the next integer.
        return i;}
                                    The same is true for pointer to
                                    objects
int main()
   demo d[3]=\{55,66,77\};
   demo *ptr=d; //simiiar to *ptr=&d[0]
   for(int i=0;i<3;i++)</pre>
       cout<<ptr->getdata()<<endl;</pre>
      ptr++;
```

Program

 Create a class student having private members marks, name and public members rollno, getdata(), printdata(). Demonstrate concept of pointer to class members for array of 3 objects.

this pointer

```
class Test
  int mark;
  float spi;
  public:
   void SetData()
  thismanierk= 70;
   this pi= 6.55;
   void DisplayData(){
     cout << "Mark= "<<mark;</pre>
     cout << "spi= "<<spi;</pre>
int main()
   Test o1;
   o1.SetData();
   o1.DisplayData();
```

this pointer

- Within member function, the members can be accessed directly, without any object or class qualification.
- But implicitly members are being accessed using this pointer

When a member function is called, it automatically passes a pointer to invoking object.

this pointer(Cont...)

- 'this' pointer represent an object that invoke or call a member function.
- It will point to the object for which member function is called.
- It is automatically passed to a member function when it is called.
- It is also called as implicit argument to all member function.

Note:

- ✓ Friend functions can not be accessed using **this** pointer, because friends are not members of a class.
- ✓ Only member functions have a this pointer.
- ✓ A static member function does not have this pointer.

```
class sample
                           this pointer (Cont...)
  int a,b;
  public:
    void input(int a, int b){
      this->a = a + b;
      this->b = a - b;
    void output(){
     cout<<"a = "<<a;
     cout << "b" = " << b;
int main()
    sample ob1;
    int a=5,b=8;
    ob1.input(a,b);
    ob1.output();
```

this pointer is used when local variable's name is same as member's name.

```
class person
                                    this pointer is used to return
   int age;
                                    reference to the calling object
   public:
      person(int x){age=x;}/
      void display(){cout<<a href="<<a href="< age;">,<age;</a>}
      person olderperson(person p)
          if (age > p.agg)
                                 --- invoking object
            return *this;←
          else
                                   argument object
            return p;
                                    When a binary operator
};
                                      overloaded, we pass only
int main()
                                      one argument to function.
                                      The other argument is
   person r(35),h(30);
   person o=r.olderperson(h);
                                      implicitly passed using this
   o.display();
                                      pointer.
```

```
class Test
  int x; int y;
public:
  Test& | setX(int a) { x = a; return *this; }
 Test& setY(int b) { y = b; return *this; }
  void print() {
  cout << "x = " << x ;
  cout << " y = " << y;
int main()
  Test obj1;
  obj1.setX(10).setY(20);
  obj1.print();
```

this pointer (Cont...)

this pointer is used to return reference to the calling object

Pointer to Derived Class

Pointer to derived class

- We can use pointers not only to the base objects but also to the objects of derived classes.
- A single pointer variable of base type can be made to point to objects belonging to base as well as derived classes.

```
Pointer to
                         ptr
                                1000
                                       Base class
                                                      1000
For example:
                                  Pointer to
                                  derived class
   Base *ptr;
                                                      2000
   Base b;
   Derived d;
   ptr = &b; //points to base object
        //We can make ptr to point to the object d as follows
   ptr = &d; //base pointer point to derived object
```

```
class Base {
public:
void showBase(){
  cout << "Base\n"; }</pre>
};
class Derv1 : public Base {
public:
                                   Derived type casted to
void showDerived(){
                                         base type
  cout << "Derv1\n"; }</pre>
};
int main(){
                                       Base pointer explicitly
   Derv1 dv1;
                                      casted into derived type
   Base* ptr;
   ptr = \&dv1;
                                       Output:
   ptr->showBase();
                                       Base
   ptr->showDerived(); //error
                                       Derv1
   ((Derv1 *)ptr)->show();
```

Pointer to derived class (Cont...)

- We can access those members of derived class which are inherited from base class by base class pointer.
- But we cannot access original member of derived class which are not inherited from base class using base class pointer.
- We can access original member of derived class using pointer of derived class.

```
Program
```

```
class base
   public:
   int b;
   void show()
     cout<<"\nb="<<b;</pre>
};
class derived : public base
   public:
   int d;
   void show()
     cout<<"\n b="<<b<<"\n d="<<d;
```

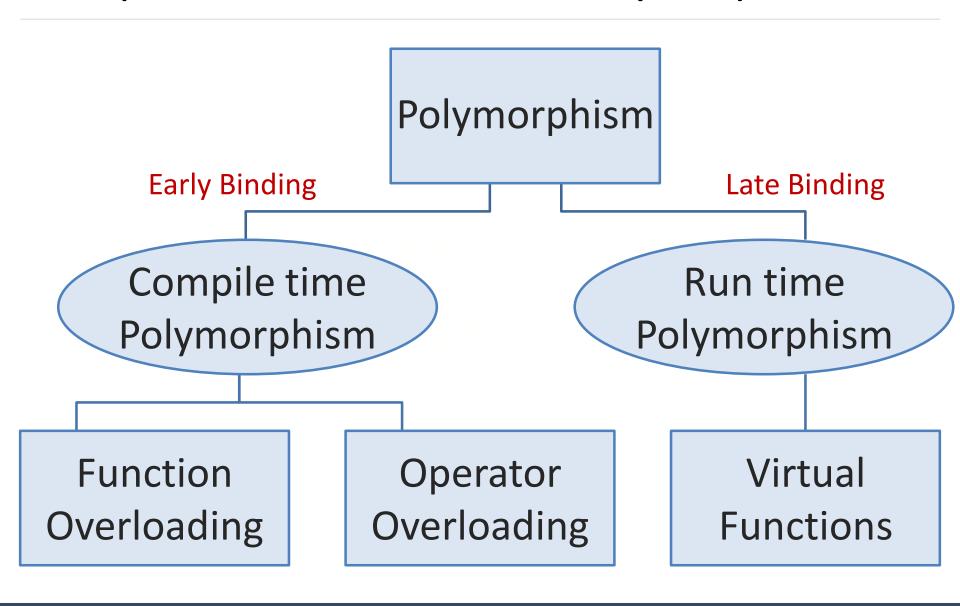

```
int main(){
                                          Program (Cont...)
base B1;
derived D1;
base *bptr;
bptr=&B1;
cout<<"\nBase class pointer assign address of base class object";</pre>
bptr->b=100;
bptr->show();
bptr=&D1;
bptr->b=200;
cout<<"\nBase class pointer assign address of derived class object";</pre>
bptr->show();
derived *dptr;
dptr=&D1;
cout<<"\nDerived class pointer assign address of derived class</pre>
object";
dptr->d=300;
dptr->show();
```

Virtual Function

Virtual Function

- A virtual function is a member function that is declared within a base class and redefined by a derived class.
- To create a virtual function, precede the function's declaration in the base class with the keyword virtual.

Compile time and Run time Polymorphism

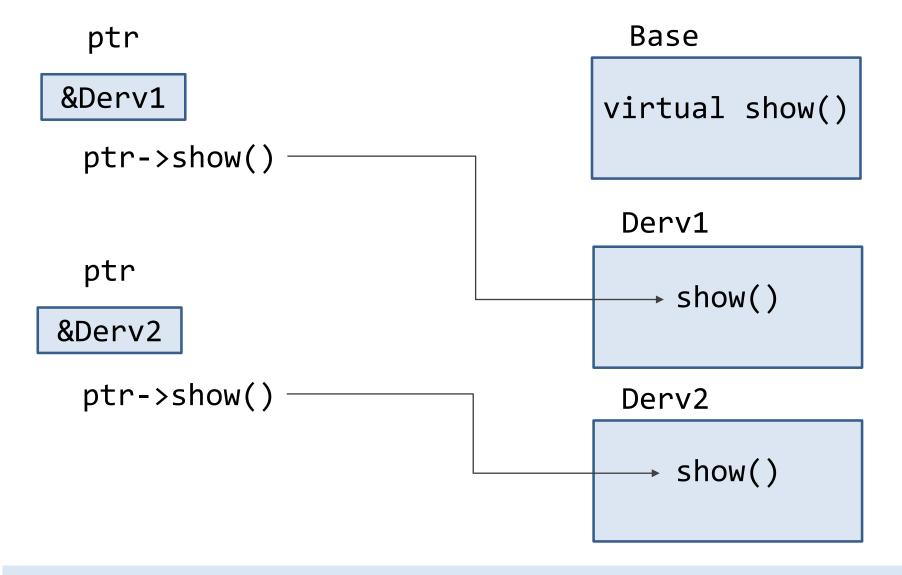

Virtual Function

- When virtual function accessed "normally," it behave just like any other type of class member function.
- But when it is accessed via a pointer it supports run time polymorphism.
- Base class and derived class have same function name and base class pointer is assigned address of derived class object then also pointer will execute base class function.
- After making virtual function, the compiler will determine which function to execute at run time on the basis of assigned address to pointer of base class.

```
class Base {
public:
virtual void show(){
  cout << "Base\n"; }</pre>
class Derv1 : public Base {
public:
void show(){
  cout << "Derv1\n"; }</pre>
class Derv2 : public Base {
public:
void show(){
  cout << "Derv2\n"; }</pre>
};
```

```
int main()
  Derv1 dv1;
  Derv2 dv2;
   Base* ptr;
   ptr = \&dv1;
   ptr->show();
   ptr = \&dv2;
  ptr->show();
```

Output: Derv1 Derv2

When a function is made virtual, C++ determines which function to use at run time based on the type of object pointed by the base pointer, rather than the type of pointer.

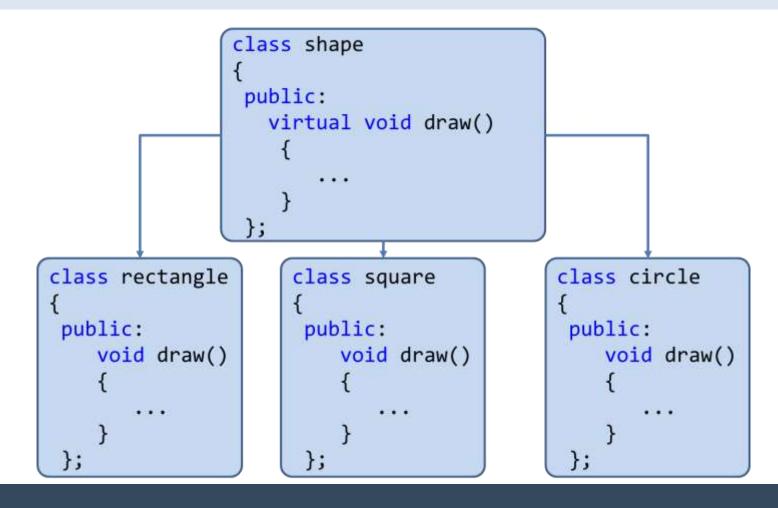

Rules for virtual base function

- 1. The virtual functions must be member of any class.
- They cannot be static members.
- They are accessed by using object pointers.
- 4. A virtual function can be a friend of another class.
- 5. A virtual function in a base class must be defined, even though it may not be used.

Pure Virtual Function

Pure Virtual Function

 A pure virtual function is virtual function that has no definition within the base class.

Pure virtual functions

- A pure virtual function means 'do nothing' function.
- We can say empty function. A pure virtual function has no definition relative to the base class.
- Programmers have to redefine pure virtual function in derived class, because it has no definition in base class.
- A class containing pure virtual function cannot be used to create any direct objects of its own.
- This type of class is also called as abstract class.

Syntax:

```
virtual void display() = 0;
OR
virtual void display() {}
```

```
Program
class Shape{
    protected:
       float x;
                               This is called abstract class
    public:
       void getData(){cin >> x;}
       virtual float calculateArea() = 0;
};
class Square : public Shape
    public:
       float calculateArea()
           return x*x; }
};
class Circle : public Shape
    public:
       float calculateArea()
       { return 3.14*x*x; }
```

```
Program
int main()
   Square s;
   Circle c;
   cout << "Enter length to calculate the area of a square:";</pre>
   s.getData();
   cout<<"Area of square: " << s.calculateArea();</pre>
   cout<<"Enter radius to calculate the area of a circle: ";</pre>
   c.getData();
   cout << "Area of circle: " << c.calculateArea();</pre>
```

Output:

Enter length to calculate the area of a square: 10

Area of square: 100

Enter radius to calculate the area of a circle: 9

Area of circle: 254.34

Abstract Class

- A class that contains at least one pure virtual function is called abstract class.
- You can not create objects of an abstract class, you can create pointers and references to an abstract class.

new and delete Operator

Memory allocation using new operator

- new is used to dynamically allocate memory
- new finds a block of the correct size and returns the address of the block.
- Assign this address to a pointer.

- new int part tells the program you want some new storage of size int.
- Then it finds the memory and returns the address.
- Next, assign the address to *pt.
- Now pt is the address and *pt is the value stored there.

Program

```
int main ()
                                                    pt
                                    55
                                                         1000
                                    1000 <
                                                         2000
   float *pt = new float;
                                  4 bytes
                                                        2 bytes
   *pt = 55;
   cout<<"value="<<*pt;</pre>
                                 value=55
   cout<<"\naddress="<<pt;</pre>
                                  address=1000
   cout<<"\nsize="<<sizeof (*pt);</pre>
                                             size=4
   cout<<"\nsize ptr="<<sizeof pt;</pre>
                                              size=2
```

Free memory using delete operator

delete operator frees memory allocated by new.

```
int * ps = new int; // allocate memory with new
. . . // use the memory
delete ps; // free memory with delete when done
```

 it doesn't remove the pointer ps itself. You can reuse ps, to point to another new allocation.

```
int * ps = new int; // valid
delete ps; // valid
delete ps; // not valid now
int jugs = 5; // valid
int * pi = &jugs; // valid
delete pi;//not allowed, memory not allocated by new
```

Thank You
